

Replication Instruction

The R code was developed using R version 4.4.1 (2024-06-14) and RStudio version 2024.04.2. This instruction uses $N=100$ in Table A1 (which is the full result of Table 1) as an example; the procedure applies to all other tables as well. This code is very tedious and complicated, running it is time consuming. Pay close attention to the bold sections, as they require careful consideration and thorough review. Please be patient. If you have any problems, please email me at bangquan@ucla.edu.

Required R Packages

The R packages needed for this replication are **lavaan** (version 0.6.19.) for structural equation modeling and **boot** for bootstrapping procedures.

```
Install.packages ("lavaan")
```

```
Install.packages ("boot")
```

Simulation Setup

1. Set up the covariance matrix to derive the residual variances (the diagonal of ψ), which will be used for simulation.

```
identity<-diag(1, 24,24)
```

```
phi<-matrix(c( 1, 0.3, 0.4,
```

```
          0.3, 1, 0.5,
```

```
          0.4, 0.5, 1
```

```
), 3,3)
```

```
ld<-matrix(c(0.65, 0.65, 0.7, 0.7, 0.7, 0.6, 0.6, 0.5,  0.5, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
```

```
          0, 0, 0, 0, 0, 0.5, 0, 0,  0.6, 0.6, 0.6, 0.7, 0.7, 0.5, 0.5, 0.55, 0, 0, 0, 0.75, 0, 0, 0, 0,
```

```
          0, 0, 0, 0, 0, 0, 0, 0,  0, 0, 0, 0, 0, 0, 0, 0.45, 0.5, 0.5, 0.5, 0.6, 0.6, 0.6, 0.7, 0.7
```

```
), nrow=24, ncol=3)
```

```
ld2<-t(ld)
```

```
psi<-diag(1,24)-diag(ld %*% phi %*% ld2)
```

```
diag(psi)
```

Note that you don't have to run covariance matrix, because the results are included in step (2) for simulation.

- Based on this covariance matrix we start setup the population and analysis models, we call them “popmodel” and “mis_model”.

```
popmodel<-'
```

```
f1 =~ 0.65*x1 + 0.65*x2 + 0.7*x3 + 0.7*x4 + 0.7*x5 + 0.7*x6 + 0.6*x7 + 0.5*x8 + 0.5*x9
```

```
f2 =~ 0.6*x9 + 0.6*x10 + 0.6*x11 + 0.7*x12 + 0.7*x13 + 0.5*x14 + 0.5*x15 + 0.65*x16 + 0.5*x6  
+ 0.75*x20
```

```
f3 =~ 0.5*x17 + 0.5*x18 + 0.5*x19 + 0.6*x20 + 0.6*x21 + 0.6*x22 + 0.7*x23 + 0.7*x24 +  
0.45*x16
```

```

```

```
x21 ~~ 0.64*x21
```

```
x22 ~~ 0.64*x22
```

```
x23 ~~ 0.51*x23
```

```
x24 ~~ 0.51*x24
```

```
,
```

```
mis_model<-'
```

```
f1 =~ x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8
```

```
f2 =~ x9 + x10 + x11 + x12 + x13 + x14 + x15 + x16
```

```
f3 =~ x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24
```

```
f3 ~~ f1
```

```
f1 ~~ f2
```

```
,
```

3. Based on the population model, we conduct Monte Carlo simulation using R package 'Lavaan', with which we obtain simulated data.

```
set.seed(105)
```

```
mydata<-simulateData(popmodel, model.type = "sem", sample.nobs=100L)
```

```
fit1 <- sem(model = mis_model, data=mydata, meanstructure=FALSE, likelihood = "wishart",  
estimator = "ML")
```

Univariate LM Test

4. We begin by performing a univariate LM test, sorting the results, and selecting the top 12 values for further analysis.

```
modindices(fit1, minimum.value = 0, sort = TRUE)[1:12,]
```

```
> modindices(fit1, minimum.value = 0, sort = TRUE)[1:12,]  
  lhs op rhs    mi    epc sepc.lv sepc.all sepc.nox  
76  f2 =~ x6 92.098 3.061 2.360 2.859 2.859  
102 f3 =~ x16 24.355 1.248 0.779 0.612 0.612  
82  f2 =~ x20 20.773 0.810 0.624 0.532 0.532  
55  f1 =~ x9 17.748 1.615 0.808 0.900 0.900  
172 x4 ~~ x8 12.349 0.151 0.151 0.356 0.356  
72  f2 =~ x2 11.601 -1.116 -0.860 -0.852 -0.852  
176 x4 ~~ x12 11.393 -0.234 -0.234 -0.350 -0.350  
171 x4 ~~ x7 10.763 0.234 0.234 0.330 0.330  
191 x5 ~~ x8 10.058 0.123 0.123 0.322 0.322  
303 x12 ~~ x15 9.999 0.229 0.229 0.334 0.334  
170 x4 ~~ x6 9.644 -0.116 -0.116 -2.400 -2.400  
73  f2 =~ x3 8.573 -0.853 -0.658 -0.687 -0.687
```

We use these 12 parameters to calculate their LM test chi-square statistics and p-values. Next, we define 'newpar' and run the `lavTestScore()` function to obtain the univariate LM test results.

```
newpar = '
f2=~x6
f3=~x16
f2=~x20
f1=~x9
x4~~x8
f2=~x2
x4~~x12
x4~~x7
x5~~x8
x12~~x15
x4~~x6
f2=~x3
'
```

```
lavTestScore(fit1, add=newpar)
```

	lhs	op	rhs	X2	df	p.value
1	f2	~	x6	92.098	1	0.000
2	f3	~	x16	24.355	1	0.000
3	f2	~	x20	20.773	1	0.000
4	f1	~	x9	17.747	1	0.000
5	x4	~	x8	12.349	1	0.000
6	f2	~	x2	11.601	1	0.001
7	x4	~	x12	11.393	1	0.001
8	x4	~	x7	10.763	1	0.001
9	x5	~	x8	10.058	1	0.002
10	x12	~	x15	9.999	1	0.002
11	x6	~	x4	9.644	1	0.002
12	f2	~	x3	8.573	1	0.003

The table above displays the parameters along with their LM chi-square values and *p*-values.

Bootstrap LM Test

- To perform the bootstrap LM test, we manually input two parameters at a time and execute the bootstrap resampling procedure. During each iteration, the model is updated by adding two parameters to 'newpar' and adjusting the values in **lavTestScore** accordingly. This process continues until all 12 parameters have been systematically incorporated into the analysis.

```
newpar = '  
f2=~x6  
f3=~x16  
'  
  
set.seed(105)  
Data<-mydata  
# Initialize the matrix to store bootstrap results  
bin.1000 <- matrix(NA, nrow = 500, ncol = 2)  
  
# Loop through bootstrap iterations  
for (i in 1:500) {  
  
  # Perform one bootstrap iteration  
  boot.res <- tryCatch({  
    # Generate bootstrap sample  
    boot.idx <- sample.int(nrow(Data), replace = TRUE)  
    Data.boot <- Data[boot.idx, ]  
  
    # Fit the SEM model  
    fit2 <- sem(model = mis_model, data = Data.boot, int.ov.free = FALSE, std.lv = FALSE,  
estimator = "ML")  
  
    # Calculate scores  
    score1 <- lavTestScore(fit2, add = newpar)$uni[1, 4]  
    score2 <- lavTestScore(fit2, add = newpar)$uni[1, 6]  
  
    # Return scores  
    list(score1 = score1, score2 = score2)  
  }, error = function(e) {  
    # If SEM model did not converge, return NULL  
    NULL  
  })  
  bin.1000[i, 1] = score1  
  bin.1000[i, 2] = score2  
}
```

```

})

# Check if boot.res is not NULL (i.e., SEM model converged)
if (!is.null(boot.res)) {
  # Update the matrix with scores
  bin.1000[i, 1] <- boot.res$score1
  bin.1000[i, 2] <- boot.res$score2
}
}

# Calculate the means of the scores
t1 <- mean(bin.1000[, 1], na.rm = TRUE)
t2 <- mean(bin.1000[, 2], na.rm = TRUE)
t1
t2

```

Note that we need to manually change these values, [1,4] and [1,6] one by one.

```

score1 <- lavTestScore(fit2, add = newpar)$uni[1, 4]
score2 <- lavTestScore(fit2, add = newpar)$uni[1, 6]

```

After running this code, we calculate t1 and t2 (the LM chi-square and p-value). Then, we update t1 and t2 to [2, 4] and [2, 6], respectively. Next, we rerun the code with these updated parameters. Afterward, we add (f2~x20) and (f2~ x20) and (f1~x9) and (f1~x9) to ‘newpar’ and execute the code again. This process is repeated until all parameters have been processed.

```

newpar = '
f2=~x6
f3=~x16
f2=~x20
f1=~x9'

```

We repeat this procedure until we finish those 12 parameters. We keep those statistically significant (p-value<0.05) parameters for bootstrap Wald test.

Bootstrap Wald Test

- To perform a bootstrap Wald test, we incorporate the bootstrap LM test suggested statistical parameters into the original analysis model, which we call it “w_model”. Note that this is very tricky to include the right parameters into the “w_model”. I would suggest following Table A1 to see which bootstrap LM test suggested

parameters to include. To distinguish these newly added parameters, we denote them as b_1 , b_2 , b_3 and so on. Note that parameters that are not statistically significant will not be included in 'w_model'. If you attempt to run the model, R will return 'NaN'. For replication purposes, we have prepared all the necessary code.

```
w_model<-'
f1 =~ x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + b4*x9
f2 =~ x9 + x10 + x11 + x12 + x13 + x14 + x15 + x16 + b1*x6 + b3*x20 + b6*x2
f3 =~ x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24 + b2*x16
f3 ~~ f1
f1 ~~ f2
x4~~b7*x12
x4~~b8*x7
x12~~b10*x15
x6~~b11*x4
'
```

After setting up the "w_model," we include the model and perform a backward stepwise procedure, constraining $b_1 = 0$, and then run the model. This provides the Wald test and its corresponding p-value. Next, we add another constraint, such as $b_2 = 0$, and repeat this process until all bootstrap LM test-suggested parameters have been evaluated.

```
set.seed(105)

con='
b1==0'

Data<-mydata
# Initialize the matrix to store bootstrap results
bin.1000 <- matrix(NA, nrow = 500, ncol = 2)

# Loop through bootstrap iterations
for (i in 1:500) {

  # Perform one bootstrap iteration
  boot.res <- tryCatch({
    # Generate bootstrap sample
    boot.idx <- sample.int(nrow(Data), replace = TRUE)
    Data.boot <- Data[boot.idx, ]

    # Fit the SEM model
```

```

fit2 <- sem(model = w_model, data = Data.boot, meanstructure = FALSE, likelihood =
"wishart", estimator = "ML")

# Calculate Wald test statistics and p-values
wald_stat <- lavTestWald(fit2, constraints = con)$stat[1]
wald_p_value <- lavTestWald(fit2, constraints = con)$p.value[1]

# Return statistics
list(stat = wald_stat, p_value = wald_p_value)
}, error = function(e) {
# If SEM model did not converge, return NULL
NULL
})

# Check if boot.res is not NULL (i.e., SEM model converged)
if (!is.null(boot.res)) {
# Update the matrix with Wald test statistics and p-values
bin.1000[i, 1] <- boot.res$stat
bin.1000[i, 2] <- boot.res$p_value
}
}

# Calculate the means of the Wald test statistics and p-values
w1 <- mean(bin.1000[, 1], na.rm = TRUE)
w2 <- mean(bin.1000[, 2], na.rm = TRUE)
w1
w2

```

Likelihood Ratio Test

7. To perform the likelihood ratio test, we first set up a base model, referred to as "m_0," which is the original analysis model. Next, we create a series of nested models, each including an additional parameter suggested by the univariate LM test—specifically, the parameters listed in "newpar."

```

m_0<-'  

f1 =~ x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8

The chi-square test statistics and p -values are presented in Table A1.

Table 2. Monte Carlo Simulation Results for Asymptotic Properties

These codes replicate the simulation results reported in Table 2. First, we set up the covariance matrix to obtain the diagonal ($\psi \setminus \psi$), which is included in the population model. Note that running this code is not necessary because the values are already part of the population model. To change the sample size, modify `sample.nobs=` [# of sample size].

```
identity<-diag(1, 24,24)
phi<-matrix(c( 1, 0.3, 0.4,
              0.3, 1, 0.5,
              0.4, 0.5, 1
), 3,3)
ld<-matrix(c(0.65, 0.65, 0.7, 0.7, 0.7, 0.6, 0.6, 0.5, 0.6, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
            0, 0, 0, 0, 0, 0.5, 0, 0, 0.6, 0.6, 0.6, 0.7, 0.7, 0.5, 0.5, 0.55, 0, 0, 0, 0.5, 0, 0, 0, 0,
            0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0.55, 0.5, 0.5, 0.5, 0.5, 0.6, 0.6, 0.7, 0.7
), nrow=24, ncol=3)
ld2<-t(ld)
psi<-diag(1,24)-diag(ld %*% phi %*% ld2)
diag(psi)
```
